

Continuous Simulation

Dr. ir. F.L.M. Delbressine

Continuous simulation

- Continuous Simulation refers to a computer model of a physical system that continuously tracks system response according to a set of equations typically involving differential equations.

Wikipedia

Difference between discrete event simulation and continuous simulation:

- **Discrete event simulation** is appropriate for systems whose state is discrete and changes at particular time point and then remains in that state for some time. An example of such a system is the number of customers in a post office: The number of customers is discrete (integer) and the number of customers only changes when someone enters the post office or finishes its business at the counter.
- **Continuous simulation** is appropriate for systems with a continuous state that changes continuously over time. An example of such a systems is the amount of liquid in a tank and or its temperature. Such a system can be described by differential equations. Continuous simulation is a technique to solve these equations numerically.

Example Continuous simulation: Bouncing Ball

$$\frac{dv}{dt} = -g$$

$$\frac{dx}{dt} = v$$

Boundary conditions:

$$x_0 = 10[m]$$

$$v_0 = 15[m/s]$$

$$g = 9.81 \left[\frac{m}{s^2} \right]$$

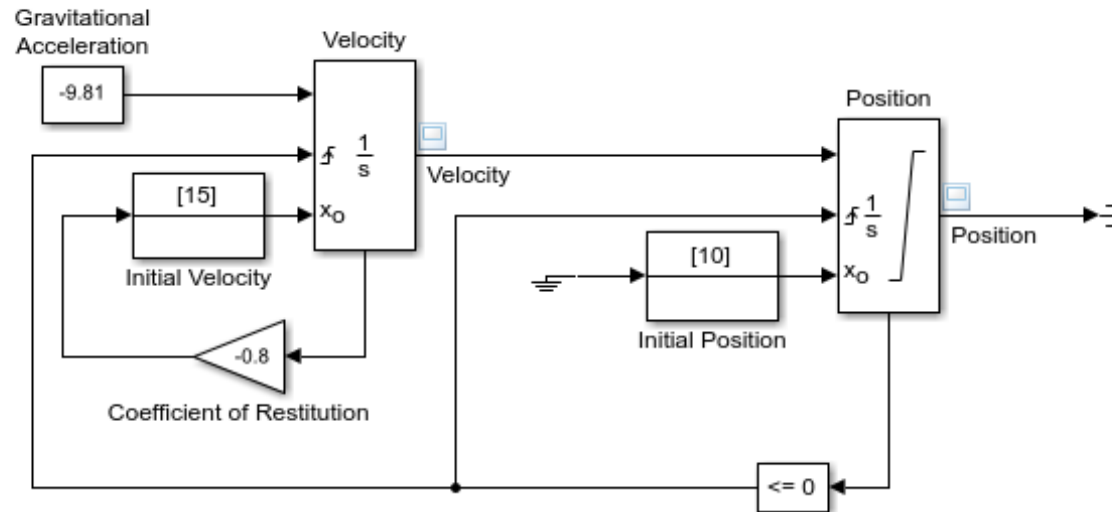

$$\text{And : } v^+ = -kv^-, x = 0$$

Two integrator model

Bouncing Ball Model

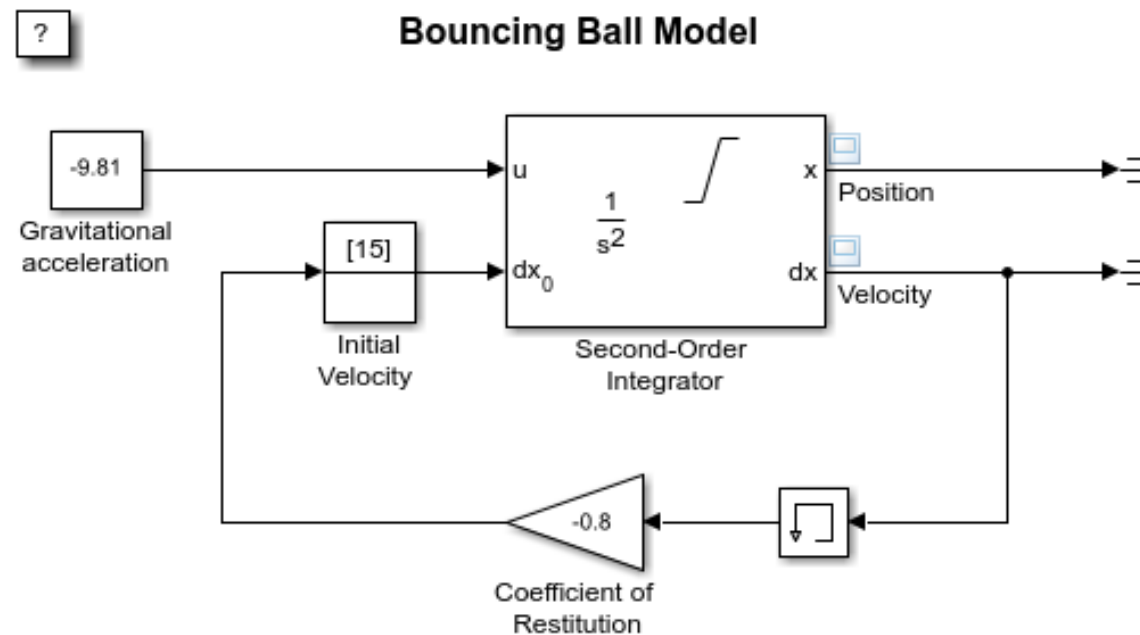

Two separate Integrators are less efficient than a single Second-Order Integrator for simulating a bouncing ball.

The state port of the position integrator and the corresponding comparison result is used to detect when the ball hits the ground and to reset both integrators.
